Immediate implantation with CAD/CAM and functional restoration in the aesthetic zone

Drs Feng Liu, Xiaorui Shi & Miaozhen Wang, China

The aesthetics are always a significant challenge during implant restoration, especially in the aesthetic zone, in addition to the full consideration required regarding function. In this article, we present a case of multiple tooth fractures due to trauma. After tooth extraction, immediate implantation and guided bone regeneration (GBR) were performed. During the prosthetic procedure, the design and transfer of the emergence profile of the soft tissue, functional design and occlusal adjustment, as well as the CAD/CAM process, were satisfactorily realized to achieve the aesthetic and functional goals.

Case report

Dental history

A 40-year-old female patient had sustained trauma to her anterior teeth caused by accidental syncope three weeks before. The clinical examination found that tooth #11 had been luxated; the crowns of teeth #12 and 21 had fractured, with the residual margin extending 3–5 mm below the gingiva and the teeth affected by Grade III mobility; and the crown of tooth #22 had fractured, with the residual margin at gingival level. There were no obvious abnormalities in the remaining teeth (Figs. 1–4). After excluding major systemic diseases, it was decided that the required fixed implant restoration with high demands regarding aesthetics and function.

Treatment procedure

Teeth #12, 21 and 22 were extracted. Tooth #11 underwent early implantation and tooth #12 immediately implantation with GBR (Figs. 5 & 6). After three months of healing, osseointegration had taken place. An implant level impression was taken for fabricating a provisional bridge supported by temporary abutments for teeth #12–22. The technician modified the shape of the artificial gingiva on the model in order to form the proper gingival curve and emergence profile, then finished the provisional bridge, while the dentist modified the gingival shape using an olive-shaped bur intraorally (Figs. 7–18).

The aesthetic and functional outcomes of the provisional restoration were checked. The tip of tooth #13 was too low to achieve a good smile line. When checking the intercuspal position (ICP) and lateral excursion using 80 μm occluding paper, tooth #13 was found to be out of contact. After reshaping the labial surface with resin, tooth #13 had good contact and guidance during ICP and lateral excursion (Figs. 19–25).

Once the aesthetic and functional outcomes had been confirmed, the anterior guidance of the provisional restoration was recorded on an articulator (Artex, Amann Girrbach) and an individual incisal guide table (Figs. 24–27). Next, the emergence profile of the provisional restoration was transferred and the cast model was made and mounted on the articulator (Figs. 28–33).

The cast model was scanned step by step to obtain a digital model and this was integrated with a virtual articulator. The anterior guidance of the virtual articulator was set according to the data from the provisional restoration. Next, the design was completed on computer and the titanium-based zirconia abutment and fixed zirconia bridge produced via CAM. After staining and glazing, the final restoration was completed (Figs. 34–41).

The final restoration demonstrated a good outcome, both aesthetically and functionally (Figs. 42–50).

Discussion

This patient came to the clinic just after the trauma, and according to the intraoral condition, immediate implantation could have been carried out. However, owing to the unexplained accidental syncope, diseases of the central neural system were to be excluded first, so delayed dental treatment was suggested.

Three weeks later, after a general physical check-up, implantation was begun. Usually operation within 48 hours after tooth extraction is considered as immediate implantation, while operation within the first six weeks after tooth extraction is considered as early implantation. Therefore, in this case, implant #11 was early implantation and implant #22 immediate implantation. The preoperative CT analysis showed that the labial side of the alveolar ridge of teeth #12, 11 and 22 was deficient, thus, GBR was needed in order to obtain sufficient bone quantity.

After three months of healing, both hard and soft tissue around the implants had been well maintained, providing a sufficient foundation for the maxillary restoration. In order to form a good gingival contour of tooth #13, the labial contour was adjusted.

Guidance on tooth #13 after reshaping of the lingual surface with resin (12 μm occluding paper, red).

ICP contact on tooth #13 after reshaping of the lingual surface with resin (12 μm occluding paper, red).

When manufacturing the final restoration, a CAD/CAM system was used. Digital models, ICP relationship and data on anterior guidance were integrated into the virtual articulation system. In the process of CAD, the precise design of both aesthetic and functional aspects could be realized.

In this case, a titanium-based zirconia abutment and zirconia bridge were used. The zirconia material used on the titanium base was a special zirconia with extremely high strength, which can guarantee excellent strength and durability of the restoration even if very thinly applied. The zirconia material used for the bridge restoration was a kind of CAD/CAM zirconia with a high translucency and 3-D multilayer colour. Without any ceramic veneer, only with a little staining and glazing, an excellent colour and translucency effect can be achieved.

This was a difficult implant-supported aesthetic restoration case. With the great efforts of the surgeons, prosthodontists and technicians, a satisfactory result was achieved.

The surgeons in this case were Drs Feng Liu and Miaozenh Wang and the prosthodontists were Drs Feng Liu and Miaozhen Wang. The restoration was completed by dental technicians Samuel Chou and Chunjia Duan.
