Interview: “Applying the 3D printing technologies of tomorrow to the supply chain problems of today”

What is your manufacturing process? Metal 3D printing works through a process called Powder Bed Fusion. Powder Bed Fusion sees a fine layer of metal powder, in our case a CE certified bio-compatible Chrome Cobalt, rolled onto a plate. A snow high-precision fibre laser is then used to selectively melt the metal powder to create the first layer of the desired shape. The accuracy of this laser is +/- 20 microns. To put this in context, a human red blood cell is about 5 microns, whilst a human hair is on average 75 microns wide.

After the laser has selectively melted the first layer, the plate drops, a new layer of powder is rolled, and the laser fires again. This process is repeated layer by layer, step by step, until the desired part is finished.

Why did you decide to do what you do in the UAE? A number of factors meant that the UAE was a great home for Sinterex. Firstly, there are some fantastic clinics and dental laboratories here which are pushing further towards digital dentistry and embracing new production techniques. We felt that we could build good partnerships. Secondly, Dubai recently set out a strategic vision to create a 3D printing hub. We see ourselves as a supplier to these dental labs and our objective is to enable them to offer digital metal CAD / CAM solutions and to move away from time-consuming and potentially error-prone manual metal work.

For future expansion, we are listening carefully to our customers in the dental industry and having some great conversations about areas of further collaboration. At some stage in the future, we are also interested in stepping out into medical customised implant manufacturing. For now though, we remain focused on delivering great products and service to our existing customers and looking to add new customers.

How can the region benefit from this technology? Both clinics and laboratories in the region can benefit significantly from this technology. For digitally-era- hed companies, those with 3D scanners and CAD design software, we offer localised production at very short lead times and much smaller prices than milling centres in Europe. For those companies which have not yet digitalised, we can help them to gain the benefits of digital production - accuracy, speed, reliability - without having to carry the costs of purchasing production equipment.

Just recently, you have printed the first 3D teeth here in Dubai, UAE; what was the process used? This project was undertaken in collaboration with Middle East Dental Laboratory, a leading dental specialist and long-term proponent of digital and 3D printing in dentistry. Sinterex had responsibility for metal 3D printing a 12-tooth bone-bridge using the Powder Bed Fusion process outlined earlier. The team at the Middle East Dental Laboratory developed the design in collaboration with the Doctor and then finished the part and applied the ceramic veneering.

What is your target market at the moment and what are your expansion plans? Our target market at the moment is dental laboratories in the Middle East region. We see ourselves as a supplier to these dental labs and our objective is to enable them to offer digital metal CAD / CAM solutions and to move away from time-consuming and potentially error-prone manual metal work.

For future expansion, we are listening carefully to our customers in the dental industry and having some great conversations about areas of further collaboration. How does your technology benefit patients? Patients benefit from gaining access to a technology which provides quicker and more accurate results than traditional manual techniques.

By Dental Tribune MEA / CAPPmea

Sinterex is a manufacturing company which specialises in the mass production of customised products using 3D printing technology (Additive Manufacturing). Dental Tribune MEA had the opportunity to meet with Julian Callanan, founder of Sinterex and ask more about the company.

How does your technology benefit patients? Patients benefit from gaining access to a technology which provides quicker and more accurate results than traditional manual techniques.
