The Concept of Progressive Smile Design and its potential impact on Cosmetic Dentistry

By Dr. Tif Qureshi, UK

Cosmetic dentistry is commonly at the forefront of everything interesting and exciting in dentistry. Hitherto, all dentistry can and should be carried out in an aesthetic way, and as a result the term "cosmetic" could apply to nearly any type of treatment, even an extraction if executed with aesthetics in mind.

The way treatment planning is carried out for smile makeovers has fundamentally been the same for some time. Recently Digital Smile Design has taken another step and has made the very best and most intelligent use of software, imaging and video to create a very powerful and emotional communication tool. This can allow a patient to see a smile makeover mockup not just on a screen as a static image but watching themselves on video and actually to trial it within their mouths also and deliver an emotional response to that preview.

Ideal smiles and fantastic results can be achieved this way and this is appropriate for patients who want perfection or is it?

The concept of progressive smile design is a little different.

The idea of PSD to allow the patient to see improvements in its staged approaches to really decide if they want a perfect smile at the end of treatment. Now of course Progressive smile design and Digital smile design are not mutually exclusive, they can be combined but commonly PSD will result in less treatment for the patient.

The Concept of Progressive Smile Design

The Concept of Progressive Smile Design often uses mixture of tooth alignment, whitening, direct bonding and contouring. Indirect treatments can certainly be considered but are only ever after the patient is able to see changes alignment, bleaching or shaping can achieve.

The logic to this approach is that we are trying to see if a patient is satisfied with small staged improvements rather than going straight to a perfect result in an irreversible way. It may well be that they do end up with a perfect smile but at least the consenting process is real, because the patient is able to see the very best in their own smile before moving forward to the irreversible stages.

Looking at this in a more extreme way, it might be the difference between a patient choosing 8-10 veneers accepting some tooth preparation to do so, and alternatively absolutely no tooth removal whatsoever with less financial and biological risk.

The case described shows a patient’s journey and how her perception of her own smile changed with progress in a progressive approach. It will give the amount of space creation to achieve alignment. From previous evidence of patient’s main complaint was her diastema, and the fact that it was removable. Once she understood that the diastema could be closed in less than 10 weeks she suddenly became keen on using the appliance.

The concept of this approach is that a patient can hold the models and really appreciate the potential outcome with a clearer picture of the proposed Archwize setup. Two days later a digital STL was sent to the Inman Aligner laboratory with the spacewize trace. The Spacewize trace revealed that the case would required 0.2mm of space creation to achieve alignment. With a diastema present, this might seem a surprise but the laterals closing towards and being rotated were already accounting for much of that space.

Impressions were taken and sent to the Inman Aligner laboratory with the spacewize trace. Two days later a digital STL was sent of the proposed Archwize setup. This was checked and the lab was instructed to create the 3d print of the proposed setup.

The patient was keen to see this before committing to understand the real potential outcome. The advantage of a 3d print over 2d images is that a patient can hold the models and really appreciate the potential outcome with a clearer picture of scale, position and shape. On viewing the models the patient was highly satisfied with the proposed outcome and could also see that the teeth still looked short and further treatment would be needed to lengthen them.

This was discussed and planned. The Inman Aligner to be constructed.

One week later it was fitted – Instructions were given and no space creation needed. The patient was to wear the appliance for 18-20 hours a day. The patient turned the mukup screw once every 3 days. After 2 weeks a significant improvement was seen.

At 4 weeks home bleaching was started using DayWhite 6% HA2O2 (Philips) using super-sealed trays. (trays with sealing grooves cut into the stone models before sucking down). She whitened for 15 minutes a day while the Inman Aligner was out of the mouth for 2 weeks.

At this appointment a little flattening of the contact was carried out to reduce the risk of a black triangle and lengthen the connector. This was done using a softer disc using the digital models for guidance. Buccal anchors were also placed to help the laterals rotate in.

At 6 weeks the diastema was closed and the teeth were noticeably whiter.

The Case

This 26 year-old lady presented inquiring if she could improve her own smile. She felt both laterals were too proned and liked the angle and vertical inclination that might be required.

The Spacewize trace revealed that the curve is then set using Spacewize TM software. The reference point sets the curve and that curve then is used to calculate the amount of potential crowding and potential space creation that might be required.

The patient was keen to see this before committing to understand the real potential outcome. The advantage of a 3d print over 2d images is that a patient can hold the models and really appreciate the potential outcome with a clearer picture of scale, position and shape. On viewing the models the patient was highly satisfied with the proposed outcome and could also see that the teeth still looked short and further treatment would be needed to lengthen them.

The patient was keen to see this before committing to understand the real potential outcome. On viewing the models the patient was highly satisfied with the proposed outcome and could also see that the teeth still looked short and further treatment would be needed to lengthen them.
and the patient was shown the new potential outline. Immediately the patient was thrilled and happy to just have no preparation composite bonding as the final part of the treatment rather than veneers.

The part of the process is vital as allowing a patient to see their teeth align and whiten often helps them to comprehend the best potential in their own natural smile before taking an irreversible route.

Two weeks later an indirect wire retainer was bonded in place after roughening the teeth and using etch and optioned with Venus Diamond Flow.

On the same day, direct composite edge bonding was carried out. Venus Diamond (Heraeus Kulzer) 01 shade dentine was placed initially to block out the visual join and B1 and B2 shade were used on the facial surfaces and blended into the surface of the teeth. The patient returned for her polishing appointment and the material was fully blended into the tooth. At this point the black triangle was closed also.

Lateral and anterior guidance was rechecked and adjusted and a new impression was taken for a night-time Essix/backup retainer.

Discussion
This case was completed in less than 10 weeks. By allowing this patient to see small changes a little at a time, she was able to see the very best potential in her own smile, and to make the decision to move to composite edges instead of just jumping straight into porcelain veneers. The long term biological and cost and economic cost also means that the risks are lower. There is certainly nothing wrong with placing porcelain veneers on a case like this, but one can see that following the logic of progressive smile design, you never really know what the patient wants unless they are able to see the very best in their own smile and they might be happy with a small amount of bleaching, alignment or bonding. Added to the fact that the long term risks of cases like this are lower, and this kind of treatment is more accessible to many more patients, one can see the potential for many patients around the world.
